

Acid/Base	
Renal Tubular Acidosis: Hyperchloremic Metabolic Acidosis w/ +Urine AG	
Not fitting?	<p>Use the "delta gap" → $[AG - 12] / [24 - \text{bicarb}]$ - compares diff btw measured and normal AG vs diff btw normal bicarb and measured bicarb to answer the question: is each decrease in the bicarb accounted for by an increase in the AG?</p> <ul style="list-style-type: none"> ■ If yes, then DGap = 0.8 to 2 → high AG metabolic acidosis (MAc) alone ■ If no and DGap <0.4 → low/normal AG MAc alone ■ If no and DGap 0.4-0.8 → low/normal AG MAc and high AG MAc ■ If no and DGap >2 → high AG MAc superimposed on chronic metabolic alkalosis or respiratory acidosis with metabolic compensation
Treatment	Directed at underlying etiology; see Metabolism section for acute management
Metabolic Alkalosis	
Chloride Responsive (urine Cl- <20 mEq/L)	Loss of gastric secretions (HCl): vomiting, NG tube drainage, thiazide and loop diuretics (urine chloride varies based on when drug was given), CF
Chloride Resistant (urine Cl- > 20 mEq/L)	<ul style="list-style-type: none"> • w/ HTN: primary hyperaldosteronism, CAH, renovascular HTN, Liddle's syndrome • w/o HTN: Bartter / Gitelman syndrome, severe K or Mg loss
Respiratory Acidosis	
DDx	<ul style="list-style-type: none"> • CNS depression • Nervous/Muscular disorders (Guillain-Barre, myasthenia gravis, botulism, muscular dystrophy) • Acute and chronic lung disease
Workup/Management	ABG/VBG, CXR, SaO ₂ , escalate respiratory support as needed
Respiratory Alkalosis	
DDx	<ul style="list-style-type: none"> • Anxiety • Hypoxia • Pain • Salicylates • Urea cycle disorders (during metabolic crisis, hyperammonemia increases respiratory drive)

Hyponatremia			
Definition	Mild: Na < 135 Moderate: Na < 130 Severe: Na < 120		
	Hypovolemic	Euvolemic	Hypervolemic
	Nonrenal sodium losses GI Skin Sequestration Renal sodium losses Diuretics Cerebral salt wasting Mineralocorticoid/ Glucocorticoid deficiency	SIADH Psychogenic polydipsia Reset osmostat Drug-induced Hypothyroidism	Edematous states Nephrotic syndrome CHF Cirrhosis Renal failure (acute or chronic)

Hyponatremia continued on next page →

Hyponatremia	
Definition	<p style="text-align: center;">Measure Serum Osmolality</p> <pre> graph TD A[Measure Serum Osmolality] --> B[Isosmolar (280 – 295 mOsm) • Pseudohyponatremia • Isonic infusion of glucose, mannitol, glycine] A --> C[Hypoosmolar (<280 mOsm)] A --> D[Hyperosmolar (>295 mOsm) • Hyperglycemia • Hypertonic infusion of glucose, mannitol] C --> E[Assess Effective Circulating Volume] E --> F[Hypovolemic] E --> G[Euvolemic] E --> H[Hypervolemic] F --> I[UNa < 20 meq/L; Uosm > 400] F --> J[UNa > 20 meq/L; Uosm > 400] I --> K[Nonrenal sodium loss] J --> L[Renal sodium loss] H --> M[UNa < 20 meq/L; Uosm > 350] H --> N[UNa > 20 meq/L; Uosm > 350] M --> O[Edematous states] N --> P[Renal failure] </pre>
Presentation	<ul style="list-style-type: none"> • Usual d/t underlying cause rather than symptoms from hyponatremia itself • Sx occur when hyponatremia evolves acutely (< 24h) & include N/V/HA → seizures, coma, and respiratory arrest
Workup	Chem 10, UA (proteinuria, hematuria, glucosuria), serum Osm (↓ in true hyponatremia. If ↑, look for hyperglycemia or other osms), urine Osm [if euvolemic, nl response to hyponatremia = suppress ADH → urine is maximally dilute (osmolality < 100 mosmol/kg, SG ≤ 1.003); abnormally conc urine + euvolemic hyponatremia = SIADH; whereas ↑ ADH i/s/o hypovolemia = appropriate ↑ in ADH], urine Na (<20 = EABV depletion, >40 = SIADH, cerebral salt wasting, diuretic use, renal failure)
Treatment	<p>Address underlying cause (volume if hypovolemic, fluid restriction if eu/hypervolemic), time course to match timing of onset (fast rx for onset <12h, slow rx for slow onset to prevent CPM)</p> <ul style="list-style-type: none"> • Acute, symptomatic: ICU admit, 3% HTS to raise [Na] by 3-5 mEq/L (give ~TBW x 5 mEq/L x 2) • Asymptomatic: calc Na deficit [(140-actual Na) x weight in kg x 0.6 for males, 0.5 for females], then give IVF with missing Na content; should not exceed 0.6 mEq/L/hr rise in [Na] • SIADH: restrict free water intake to match insensible losses + UOP; use vaptans if severe

Hypernatremia	
Definition	Serum sodium >145 mEq/L
Etiology	Excessive water loss (GI losses / Diuretics / Central or nephrogenic DI (see endocrine section) / Osmotic diuresis / Increased insensible losses / Impaired thirst mechanism) vs excessive salt intake
Clinical Manifestations	Lethargy, irritability, MS changes; typically presents w/ sx of underlying cause
Exam	Check volume status, neurologic exam, mental status
Workup	UA, chem 10, urine osm (appropriate response to hyperNa □ ↑ ADH □ concentrated urine. Inappropriately dilute urine i/s/o hyperNa □ think DI), serum osm (Uosm < Sosm □ think DI)
Management	<ul style="list-style-type: none"> • For hypernatremic dehydration, calc free water deficit: (Current Na/Desired Na -1) x TBW (weight in kg * 0.6 for males, 0.5 for females) = water deficit in liters; replace ½ of FWD w/in 24h, then remainder over next 1-2 days, and replace maintenance + ongoing losses. Avoid ↓ Na⁺ by >15 mEq/L over 24h (0.5 mEq/L/hr) d/t risk of cerebral edema. • If due to DI, see endo section for management
